The selection of appropriate responses and the withholding of inappropriate responses are central to our ability to respond appropriately in a changing environment. Response selection is generally assumed to be a more automatic process than the later control of cognitive information in working memory. Here, we show that the negative affective state induced by the presentation of emotional stimuli primes the selection of action responses and that such effects are modulated by the time available for response selection, i.e., a time constraint. These results demonstrate that the emotional state of a given individual, i.e., the pre-response emotional state, modulates the information available for response selection, suggesting an important role for emotions in modulating the cognitive control mechanisms involved in response selection.import { assert } from './utils'; describe('serializer', () => { it('should serialize objects', () => { const obj = { a: 1 }; assert.deepStrictEqual(serializer(obj), { a: 1 }); const v1: any = { a: 1 }; const v2: any = { b: 1 }; const v3: any = { c: 1 }; const v4: any = { d: 1 }; assert.deepStrictEqual(serializer(v1), { a: 1 }); assert.deepStrictEqual(serializer(v2), { b: 1 }); assert.deepStrictEqual(serializer(v3), { c: 1 }); assert.deepStrictEqual(serializer(v4), { d: 1 }); it('should be able to serialize non-objects', () => { const nonObject = {}; assert.deepStrictEqual(serializer(nonObject), {});
